Applications of clustering in IR

Application	What is clustered?	Benefit	Example
Search result clustering	search results	more effective infor- mation presentation to user	
Scatter-Gather	(subsets of) col- lection	alternative user inter- face: "search without typing"	
Collection clustering	collection	effective information presentation for ex- ploratory browsing	McKeown et al. 2002, news.google.com
Cluster-based retrieval	collection	higher efficiency: faster search	Salton 1971

K-means algorithm

$$\begin{array}{ll} \mathsf{K}\text{-MEANS}(\{\vec{x}_1,\ldots,\vec{x}_N\},\mathsf{K}) \\ 1 & (\vec{s}_1,\vec{s}_2,\ldots,\vec{s}_K) \leftarrow \text{SELECTRANDOMSEEDS}(\{\vec{x}_1,\ldots,\vec{x}_N\},\mathsf{K}) \\ 2 & \text{for } k \leftarrow 1 \text{ to } \mathsf{K} \\ 3 & \text{do } \vec{\mu}_k \leftarrow \vec{s}_k \\ 4 & \text{while stopping criterion has not been met} \\ 5 & \text{do for } k \leftarrow 1 \text{ to } \mathsf{K} \\ 6 & \text{do } \omega_k \leftarrow \{\} \\ 7 & \text{for } n \leftarrow 1 \text{ to } \mathsf{N} \\ 8 & \text{do } j \leftarrow \arg\min_{j'} |\vec{\mu}_{j'} - \vec{x}_n| \\ 9 & \omega_j \leftarrow \omega_j \cup \{\vec{x}_n\} \quad (reassignment \ of \ vectors) \\ 10 & \text{for } k \leftarrow 1 \text{ to } \mathsf{K} \\ 11 & \text{do } \vec{\mu}_k \leftarrow \frac{1}{|\omega_k|} \sum_{\vec{x} \in \omega_k} \vec{x} \quad (recomputation \ of \ centroids) \\ 12 & \text{return } \{\vec{\mu}_1,\ldots,\vec{\mu}_K\} \end{array}$$

Initialization of K-means

- Random seed selection is just one of many ways *K*-means can be initialized.
- Random seed selection is not very robust: It's easy to get a suboptimal clustering.
- Better heuristics:
 - Select seeds not randomly, but using some heuristic (e.g., filter out outliers or find a set of seeds that has "good coverage" of the document space)
 - Use hierarchical clustering to find good seeds (next class)
 - Select *i* (e.g., i = 10) different sets of seeds, do a *K*-means clustering for each, select the clustering with lowest RSS

- Bisecting K-means
- How to label clusters automatically

Outline

Introduction

Single-link/Complete-link

- 4 Centroid/GAAC
- 5 Labeling clusters

6 Variants

Hierarchical clustering

Our goal in hierarchical clustering is to create a hierarchy like the one we saw earlier in Reuters:

Hierarchical agglomerative clustering (HAC)

- HAC creates a hierachy in the form of a binary tree.
- Assumes a similarity measure for determining the similarity of two clusters.
- Up to now, our similarity measures were for documents.
- We will look at four different cluster similarity measures.

HAC: Basic algorithm

- Start with each document in a separate cluster
- Then repeatedly merge the two clusters that are most similar
- Until there is only one cluster.
- The history of merging is a hierarchy in the form of a binary tree.
- The standard way of depicting this history is a dendrogram.

A dendrogram

- The history of mergers can be read off from bottom to top.
- The horizontal line of each merger tells us what the similarity of the merger was.
 We can cut the
- dendrogram at a particular point (e.g., at 0.1 or 0.4) to get a flat clustering.

Divisive clustering

- Divisive clustering is top-down.
- Alternative to HAC (which is bottom up).
- Divisive clustering:
 - Start with all docs in one big cluster
 - Then recursively split clusters
 - Eventually each node forms a cluster on its own.
- \rightarrow Bisecting K-means at the end
- For now: HAC (= bottom-up)

Naive HAC algorithm

```
SIMPLEHAC(d_1, \ldots, d_N)
  1 for n \leftarrow 1 to N
 2 do for i \leftarrow 1 to N
 3
           do C[n][i] \leftarrow SIM(d_n, d_i)
           I[n] \leftarrow 1 (keeps track of active clusters)
 4
     A \leftarrow [] (collects clustering as a sequence of merges)
 5
 6 for k \leftarrow 1 to N-1
  7
      do \langle i, m \rangle \leftarrow \arg \max_{\{\langle i, m \rangle : i \neq m \land I[i] = 1 \land I[m] = 1\}} C[i][m]
 8
           A.APPEND(\langle i, m \rangle) (store merge)
 9
           for i \leftarrow 1 to N
10
           do (use i as representative for \langle i, m \rangle)
                 C[i][i] \leftarrow SIM(\langle i, m \rangle, j)
11
                C[i][i] \leftarrow SIM(\langle i, m \rangle, j)
12
           I[m] \leftarrow 0 (deactivate cluster)
13
14
      return A
```

Computational complexity of the naive algorithm

- First, we compute the similarity of all $N \times N$ pairs of documents.
- Then, in each of N iterations:
 - We scan the $O(N \times N)$ similarities to find the maximum similarity.
 - We merge the two clusters with maximum similarity.
 - We compute the similarity of the new cluster with all other (surviving) clusters.
- There are O(N) iterations, each performing a $O(N \times N)$ "scan" operation.
- Overall complexity is $O(N^3)$.
- We'll look at more efficient algorithms later.

Key question: How to define cluster similarity

• Single-link: Maximum similarity

- Maximum similarity of any two documents
- Complete-link: Minimum similarity
 - Minimum similarity of any two documents
- Centroid: Average "intersimilarity"
 - Average similarity of all document pairs (but excluding pairs of docs in the same cluster)
 - This is equivalent to the similarity of the centroids.
- Group-average: Average "intrasimilarity"
 - Average similary of all document pairs, including pairs of docs in the same cluster

Cluster similarity: Example

Single-link: Maximum similarity

Complete-link: Minimum similarity

Centroid: Average intersimilarity

intersimilarity = similarity of two documents in different clusters

Group average: Average intrasimilarity

intrasimilarity = similarity of any pair, including cases where the two documents are in the same cluster

Cluster similarity: Larger Example

Single-link: Maximum similarity

Complete-link: Minimum similarity

Centroid: Average intersimilarity

Group average: Average intrasimilarity

Outline

2 Introduction

- Single-link/Complete-link
- 4 Centroid/GAAC
- 5 Labeling clusters

6 Variants

Single link HAC

- The similarity of two clusters is the maximum intersimilarity the maximum similarity of a document from the first cluster and a document from the second cluster.
- Once we have merged two clusters, how do we update the similarity matrix?
- This is simple for single link:

 $\operatorname{SIM}(\omega_i, (\omega_{k_1} \cup \omega_{k_2})) = \max(\operatorname{SIM}(\omega_i, \omega_{k_1}), \operatorname{SIM}(\omega_i, \omega_{k_2}))$

This dendrogram was produced by single-link

- Notice: many small There is no balanced to the main cluster members) being added 2-cluster or 3-cluster clusters (1 or 2
- dendrogram. derived by cutting the clustering that can be

Complete link HAC

- The similarity of two clusters is the minimum intersimilarity the minimum similarity of a document from the first cluster and a document from the second cluster.
- Once we have merged two clusters, how do we update the similarity matrix?
- Again, this is simple:

$$\operatorname{SIM}(\omega_i, (\omega_{k_1} \cup \omega_{k_2})) = \min(\operatorname{SIM}(\omega_i, \omega_{k_1}), \operatorname{SIM}(\omega_i, \omega_{k_2}))$$

• We measure the similarity of two clusters by computing the diameter of the cluster that we would get if we merged them.

Complete-link dendrogram

- Notice that this dendrogram is much more balanced than the single-link one.
 We can create a 2-cluster clustering
- We can create a 2-cluster clustering with two clusters of about the same
- size.

Exercise: Compute single and complete link clusterings

Single-link clustering

Complete link clustering

Single-link vs. Complete link clustering

Single-link: Chaining

straggly clusters. For most applications, these are undesirable.

What 2-cluster clustering will complete-link produce?

Complete-link: Sensitivity to outliers

- The complete-link clustering of this set splits d₂ from its right neighbors – clearly undesirable.
- The reason is the outlier d_1 .
- This shows that a single outlier can negatively affect the outcome of complete-link clustering.
- Single-link clustering does better in this case.

Outline

2 Introduction

- Single-link/Complete-link
- 4 Centroid/GAAC
- 5 Labeling clusters

6 Variants

Centroid HAC

- The similarity of two clusters is the average intersimilarity the average similarity of documents from the first cluster with documents from the second cluster.
- A naive implementation of this definition is inefficient (O(N²)), but the definition is equivalent to computing the similarity of the centroids:

SIM-CENT
$$(\omega_i, \omega_j) = \vec{\mu}(\omega_i) \cdot \vec{\mu}(\omega_j)$$

- Hence the name: centroid HAC
- Note: this is the dot product, not cosine similarity!

Exercise: Compute centroid clustering

Centroid clustering

Inversion in centroid clustering

- In an inversion, the similarity increases during a merge sequence. Results in an "inverted" dendrogram.
- Below: Similarity of the first merger (d₁ ∪ d₂) is -4.0, similarity of second merger ((d₁ ∪ d₂) ∪ d₃) is ≈ -3.5.

Inversions

- Hierarchical clustering algorithms that allow inversions are inferior.
- The rationale for hierarchical clustering is that at any given point, we've found the most coherent clustering for a given K.
- Intuitively: smaller clusterings should be more coherent than larger clusterings.
- An inversion contradicts this intuition: we have a large cluster that is more coherent than one of its subclusters.
- The fact that inversions can occur in centroid clustering is a reason not to use it.

Group-average agglomerative clustering (GAAC)

- GAAC also has an "average-similarity" criterion, but does not have inversions.
- The similarity of two clusters is the average intrasimilarity the average similarity of all document pairs (including those from the same cluster).
- But we exclude self-similarities.

Group-average agglomerative clustering (GAAC)

• Again, a naive implementation is inefficient $(O(N^2))$ and there is an equivalent, more efficient, centroid-based definition:

$$\operatorname{SIM-GA}(\omega_i, \omega_j) =$$

$$\frac{1}{(N_i+N_j)(N_i+N_j-1)}[(\sum_{d_m\in\omega_i\cup\omega_j}\vec{d}_m)^2-(N_i+N_j)]$$

• Again, this is the dot product, not cosine similarity.

Which HAC clustering should I use?

- Don't use centroid HAC because of inversions.
- In most cases: GAAC is best since it isn't subject to chaining and sensitivity to outliers.
- However, we can only use GAAC for vector representations.
- For other types of document representations (or if only pairwise similarities for documents are available): use complete-link.
- There are also some applications for single-link (e.g., duplicate detection in web search).

Flat or hierarchical clustering?

- For high efficiency, use flat clustering (or perhaps bisecting *k*-means)
- For deterministic results: HAC
- When a hierarchical structure is desired: hierarchical algorithm
- HAC also can be applied if K cannot be predetermined (can start without knowing K)

Outline

2 Introduction

- Single-link/Complete-link
- 4 Centroid/GAAC
- **5** Labeling clusters

Major issue in clustering - labeling

- After a clustering algorithm finds a set of clusters: how can they be useful to the end user?
- We need a pithy label for each cluster.
- For example, in search result clustering for "jaguar", The labels of the three clusters could be "animal", "car", and "operating system".
- Topic of this section: How can we automatically find good labels for clusters?

Exercise

- Come up with an algorithm for labeling clusters
- Input: a set of documents, partitioned into K clusters (flat clustering)
- Output: A label for each cluster
- Part of the exercise: What types of labels should we consider? Words?

Discriminative labeling

- To label cluster ω , compare ω with all other clusters
- Find terms or phrases that distinguish ω from the other clusters
- We can use any of the feature selection criteria we introduced in text classification to identify discriminating terms: mutual information, χ^2 and frequency.
- (but the latter is actually not discriminative)

Non-discriminative labeling

- Select terms or phrases based solely on information from the cluster itself
 - E.g., select terms with high weights in the centroid (if we are using a vector space model)
- Non-discriminative methods sometimes select frequent terms that do not distinguish clusters.
- For example, MONDAY, TUESDAY, ... in newspaper text

Using titles for labeling clusters

- Terms and phrases are hard to scan and condense into a holistic idea of what the cluster is about.
- Alternative: titles
- For example, the titles of two or three documents that are closest to the centroid.
- Titles are easier to scan than a list of phrases.

Cluster labeling: Example

		labeling method				
	$\# \operatorname{docs}$	centroid	mutual information	title		
4	622	oil plant mexico production crude power000refinerygas bpd	plant oil production barrels crude bpd mexico dolly capaci- typetroleum	MEXICO: Hurricane Dolly heads for Mex- ico coast		
9	1017	police security rus - sian people military peace killed told groznycourt	police killed military security peace told troops forcesrebels people	RUSSIA: Russia's Lebed meets rebel chief in Chechnya		
10	1259	00 000 tonnes traders futures wheat prices centsseptember tonne	delivery traders fu- tures tonne tonnes desk wheat prices 000 00	USA: Export Business - Grain/oilseeds com- plex		

• Three methods: most prominent terms in centroid, differential labeling using MI, title of doc closest to centroid

• All three methods do a pretty good job.

Outline

2 Introduction

- Single-link/Complete-link
- 4 Centroid/GAAC
- 5 Labeling clusters

Bisecting K-means: A top-down algorithm

- Start with all documents in one cluster
- Split the cluster into 2 using K-means
- Of the clusters produced so far, select one to split (e.g. select the largest one)
- Repeat until we have produced the desired number of clusters

Bisecting K-means

BISECTINGKMEANS (d_1, \ldots, d_N) 1 $\omega_0 \leftarrow \{\vec{d}_1, \ldots, \vec{d}_N\}$ 2 *leaves* $\leftarrow \{\omega_0\}$ 3 for $k \leftarrow 1$ to K - 14 do $\omega_k \leftarrow \text{PICKCLUSTERFROM}(leaves)$ 5 $\{\omega_i, \omega_j\} \leftarrow \text{KMEANS}(\omega_k, 2)$ 6 *leaves* $\leftarrow |eaves \setminus \{\omega_k\} \cup \{\omega_i, \omega_j\}$

7 return leaves

Bisecting K-means

- If we don't generate a complete hierarchy, then a top-down algorithm like bisecting *K*-means is much more efficient than HAC algorithms.
- But bisecting K-means is not deterministic.
- There are deterministic versions of bisecting *K*-means (see resources at the end), but they are much less efficient.

Efficient single link clustering

```
SINGLELINKCLUSTERING(d_1, \ldots, d_N, K)
     for n \leftarrow 1 to N
 1
 2 do for i \leftarrow 1 to N
 3
          do C[n][i].sim \leftarrow SIM(d_n, d_i)
 4
               C[n][i].index \leftarrow i
 5
     I[n] \leftarrow n
 6
      NBM[n] \leftarrow \arg \max_{X \in \{C[n][i]: n \neq i\}} X.sim
 7 A \leftarrow []
 8 for n \leftarrow 1 to N - 1
     do i_1 \leftarrow \arg \max_{\{i:I[i]=i\}} NBM[i].sim
 9
10 i_2 \leftarrow I[NBM[i_1]].index]
11 A.APPEND(\langle i_1, i_2 \rangle)
12 for i \leftarrow 1 to N
13 do if I[i] = i \land i \neq i_1 \land i \neq i_2
14
                  then C[i_1][i].sim \leftarrow C[i][i_1].sim \leftarrow \max(C[i_1][i].sim, C[i_2][i].sim)
15
               if I[i] = i_2
16
                  then I[i] \leftarrow i_1
           NBM[i_1] \leftarrow \arg \max_{X \in \{C[i_1][i]: I[i]=i \land i \neq i_1\}} X.sim
17
18
      return A
```

Time complexity of HAC

- The single-link algorithm we just saw is $O(N^2)$.
- Much more efficient than the $O(N^3)$ algorithm we looked at earlier!
- There are also $O(N^2)$ algorithms for complete-link, centroid and GAAC.

Combination similarities of the four algorithms

clustering algorithm	$sim(\ell, k_1, k_2)$	
single-link	$\max(sim(\ell, k_1), sim(\ell, k_2))$	
complete-link	$\min(sim(\ell, k_1), sim(\ell, k_2))$	
centroid	$\left(\frac{1}{N_m}\vec{v}_m\right)\cdot\left(\frac{1}{N_\ell}\vec{v}_\ell\right)$	
group-average	$\left \frac{1}{(N_m + N_\ell)(N_m + N_\ell - 1)} [(\vec{v}_m + \vec{v}_\ell)^2 - (N_m + N_\ell)] \right $	

Comparison of HAC algorithms

method	combination similarity	time compl.	optimal?	comment	
single-link	max intersimilarity of any 2 docs	$\Theta(N^2)$	yes	chaining effect	
complete-link	min intersimilarity of any 2 docs	$\Theta(N^2 \log N)$	no	sensitive to outliers	
group-average	average of all sims	$\Theta(N^2 \log N)$	no	best choice for most applications	
centroid	average intersimilarity	$\Theta(N^2 \log N)$	no	inversions can occur	

What to do with the hierarchy?

- Use as is (e.g., for browsing as in Yahoo hierarchy)
- Cut at a predetermined threshold
- Cut to get a predetermined number of clusters K
 - Ignores hierarchy below and above cutting line.

- Introduction to hierarchical clustering
- Single-link and complete-link clustering
- Centroid and group-average agglomerative clustering (GAAC)
